RESULTS OF SCREENING TESTS WITH MATERIALS
EVALUATED AS INSECTICIDES, MITICIDES, AND REPELLENTS
at the
ORLANDO, FLA., LABORATORY
APRIL 1942 TO APRIL 1947

PART I. INTRODUCTION

By E. F. Knipling, L. C. McAlister, Jr., and H. A. Jones

In April 1942 investigations were started at the Orlando, Fla., laboratory to develop control measures for certain insects and arachnids of importance to the armed forces. In the course of these investigations many insecticides, miticides, and insect repellents were evaluated by simple laboratory procedure in order to eliminate from further consideration ineffective chemicals, and to obtain leads for more precise and detailed studies of the promising materials.

In the first few months of study emphasis was placed on compounds that were known to possess either insecticidal or repellent properties, to determine their value and to recommend materials for immediate use in the control of the insects under investigation at that time. Consequently, many of the materials included in this report had been tested previously as insecticides by Bushland (1), Bushland and King (2), Swingle et al. (13, 14), and many others. As the work progressed, however, it became necessary to search for new compounds in an endeavor to find specific treatments for certain purposes or to improve on materials already in use.

Most emphasis was placed on the control of human lice, mosquitoes, and chiggers (mites), although a wide variety of problems relating to insects were investigated (Knipling 9, Knipling and Dove 10). This report lists the chemicals tested and records

their effectiveness as insecticides, miticides, or repellents against the different species employed. Most of the members of the staff at the Orlando laboratory took part in the investigations. It was not practicable or desirable to include as authors all investigators who were concerned in the undertaking. The authors are appreciative of the assistance given by various staff members who took part in carrying out the screening program.

In the investigations on the control of human lice, DDT was among the first few hundred materials tested; however, all the materials subsequently received were also routinely evaluated. Although DDT proved extremely effective, it acts rather slowly and is not ovicidal. Since a faster killing agent was desirable, and an ovicide was required for certain preparations, all the chemicals obtained were studied to determine their toxicity to lice, their speed of insecticidal action, and their ovicidal value. The methods employed and the results obtained are discussed in Part II.

In the research on mosquito larvicides a number of materials were tested before DDT was shown to be exceptionally effective; however, all the materials received later were routinely tested against larvae of Anopheles quadrimaculatus Say. The test methods and results are discussed in Part III.

Studies on miticides required extensive investigations in a relatively unexplored field to find materials that would be effective when impregnated in clothing. The materials tested included practically all the synthetic organic chemicals received at the laboratory, and the results obtained are discussed in Part IV.

One of the major problems in the investigations on mosquitoes was the development of repellents that could be applied to the skin and that would remain effective for several hours under various conditions and against a wide range of species. Various chemicals, principally solids, were also tested to determine their repellent value when used as a treatment for clothing. These studies are discussed in Part V.

More than 10,000 samples were received and tested at the laboratory, but only about 7,000 are listed in this report. Most of the remaining samples were mixtures, such as louse powders, repellent compositions, and other insecticide and repellent formulations. Several hundred compounds were considered as confidential by the sources submitting them and are not included.

By presenting the results of all these tests in one combined table, it is possible to compare the efficiency of the different materials against different insects. This procedure, however, does

not allow a presentation of exact mortalities. The chemicals have therefore been classified according to four arbitrary categories, or groups, designated by number according to their value for the use indicated in the tests. The least effective materials are considered to be in group 1 and those chemicals showing greatest promise for possible practical application in group 4. A more precise explanation of each group in the various types of tests is given on pages 20-21.

More detailed data obtained with the better chemicals will be reported elsewhere. This report should be useful as a guide to other entomologists in choosing selected materials for further testing against other insects and arthropods, and it should also prove valuable to chemists in the preparation of other candidate insecticides, miticides, and insect repellents.

The materials have been listed in the table in alphabetical order. In general, names of compounds as submitted by the various sources have not been changed provided they were correct and as descriptive as possible. Only the simplest change possible has been made to make a name correct or completely descriptive of the compound. Except in the case of esters, names have been written without rearrangement, i.e., 2,5-dimethylacetophenone, instead of acetophenone, 2,5-dimethyl-. Esters have been named with the acid first, i.e., acetic acid, n-amyl ester, instead of n-amyl acetate. In general, if a reasonably definite chemical name for a substance with a trade name was available, the chemical name has been used in indexing the material followed by the trade name in parentheses. If, however, the chemical composition was indefinite, the procedure has been reversed.

Compounds for testing have been obtained from three general sources--(1) the Division of Insecticide Investigations of the Bureau of Entomology and Plant Quarantine; (2) other government agencies, including university groups operating under the Office of Scientific Research and Development; and (3) commercial sources. Most of the compounds from the Division of Insecticide Investigations were prepared especially for tests as insecticides in connection with their regular program, although this Division also prepared a considerable number of compounds for tests as repellents under the O.S.R.D. program.

Beginning about June 1944 several universities, under the O.S.R.D. program, prepared compounds especially for tests as repellents or submitted materials available from their stock shelves. For those interested in compounds prepared under this program, the Orlando code numbers assigned to materials from the university groups are as follows:

Columbia University	4900-4999
Harvard University	5500-5999 and 12000-12225
University of Illinois	11000-11320
University of Maryland	6000-6631
University of Minnesota	10000-10065
Ohio State University	7000-7499 and 13000-13242
Stanford University	10500-10594
University of Wisconsin	11500-11803

Under the same program the Division of Insecticide Investigations prepared samples 5,000 to 5,104. This Division also submitted about 900 materials as part of the regular testing program. Compounds were also submitted by such government agencies as the regional laboratories of the U. S. Bureau of Agricultural and Industrial Chemistry and the Chemical Warfare Service.

Early in the testing program most of the chemicals from commercial sources were obtained by purchase. Later a number of companies cooperated by submitting materials particularly for tests as insect repellents. The following companies submitted substantial numbers of samples:

American Cyanamid and Chemical Corp.	Killgore Development Corp.
Atlas Powder Co.	Monsanto Chemical Co.
Carbide and Carbon Chemicals Corp.	Orbis Products Corp.
Dodge and Olcott	Rohm and Haas Co.
Dow Chemical Co.	Socony-Vacuum Oil Co.
E. I. du Pont de Nemours and Co.	Sowa Chemical Co.
General Chemical Co.	Velsicol Corp.
Hercules Powder Co.	

More than 20 other companies submitted smaller numbers of materials.

PART II. EVALUATION OF MATERIALS AS LOUSICIDES

By G. W. Eddy, N. B. Carson, and R. C. Bushland

Approximately 7,000 materials were tested as toxicants against the body louse (Pediculus humanus corporis Deg.) An attempt was made to obtain information on the initial kill and lasting properties, the ovicidal properties, and the speed of knock-down of each compound. The beaker test method of obtaining data on the toxicity of materials previously untried as lousicides was a simple screening technique developed by Bushland et al. (3). Other methods not discussed here were used for making further evaluations of the more promising materials. The materials in group 4 have been discussed by Eddy and Carson (6).

Evaluation of Initial Kill and Lasting Properties

To determine the initial kill and lasting properties for the different compounds against the body louse, circular woolen cloth pads, 1½ inches in diameter, were dipped in 1-percent acetone solutions of the test materials. The compounds not soluble in acetone were dissolved in chloroform, benzene, ether, alcohol, water, or some other suitable volatile solvent. The impregnated pads were suspended on pins and allowed to dry at room temperature for 1 to 2 hours. Individual pads together with 10 young adult lice were then placed in 50-ml. beakers (fig. 1) and exposed at 30° C. and at a relative humidity of 75 to 80 percent for 24 hours. If a material gave complete kill or knock-down within this period, new lice were placed in the beakers daily until normal lice survived. All the materials which gave complete kill or knock-down for 10 days or more were placed in group 4.

Out of a total of 7,028 compounds tested, 4,916, or 70 percent, are in group 1; 793, or 11 percent, in group 2; 1,034, or 15 percent, in group 3; and only 285, or 4 percent, in group 4.

The beaker method proved to be an efficient and rapid technique for making preliminary evaluations of previously untried compounds as lousicides. Since materials that had been shown to be toxic to lice by certain other procedures also proved toxic by this method, it appeared to be a reliable screening test method. However, materials effective by the beaker method were not necessarily good lousicides. Most materials when tested in powder form proved relatively ineffective. The standard adopted for the best group (group 4) was relatively low. DDT and certain other materials, for example, when tested by the screening technique used, remain effective for months, whereas the minimum standard for the best group was 11 days or more. This low standard was adopted so that an effective and possibly practical lousicide would not be overlooked.

Evaluation as Ovicides

At the beginning of the louse-control investigations an ovicide was needed, because there was no formula available for killing lice that would remain completely effective throughout the incubation period of the eggs. The use of a long-lasting compound such as DDT all but did away with the need of a body louse ovicide. The research on ovicides was continued, however, since an efficient ovicide was needed for the control of the head and crab louse, and also since such information would prove of value in the selection of an all-purpose lousicide.

The method of evaluating the various compounds as ovicides is described as follows: Cloth pads, approximately ½-inch square (fig. 2) bearing 100 to 200 eggs 4 to 6 days old were dipped in

alcoholic solutions of the test compounds, allowed to dry, and then placed in an incubator held at 30° C. and a relative humidity of approximately 80 percent. The compounds not soluble in alcohol were dissolved in some other suitable nonovicidal solvent such as acetone, chloroform, benzene, ether, or water. The percent kill was determined only after hatching was completed in the untreated control lot of eggs. Usually about 96 to 100 percent of the untreated eggs hatched.

Routinely, all the materials were tested at 5 percent. Materials giving complete kill of eggs at this concentration were also tested at 1 percent. The materials which gave complete kill at 1 percent or less were placed in group 4.

Of the 6,975 materials tested as ovicides, 3,950, or 57 percent, were rated as 1; 1,707, or 24 percent, as 2; 1,003, or 14 percent, as 3; and 315, or 5 percent, as 4.

Compounds readily available and economical, or desirable for other reasons, which were given a rating of 2 or even 1 should not be entirely discounted as possible louse ovicides, since they might give complete kill at higher concentrations.

Evaluation as Knock-down Agents

Since it was important to find an insecticide that was fast-acting against the body louse and other medically important insects, observations were made on the knock-down properties of the various compounds by the beaker test method. After the lice were placed on the impregnated cloth pads, observations were made after 15 and 30 minutes and 1 and 3 hours. Several hundred compounds were also checked after 6 hours. Only the materials which gave complete knock-down of lice in 1 hour or less were rated as 4.

Except for a few materials, the compounds which did not cause knock-down did not kill lice. Most of the better knock-down agents proved either poor lousicides or not exceptionally good as ovicides. Of the 7,023 compounds tested, 6,633, or 94 percent, were rated as 1 and 2; 220, or 3 percent, as 3; and 170, or 3 percent, as 4. Compounds rated as 2 were not of great interest since they were considered too slow.

Although one of the objectives of the louse-testing program was to find a single material that was highly effective against lice, and one that was also ovicidal and possessed rapid paralytic action on lice, only a few of the materials possessed all three properties and most of these had some objectionable characteristic, such as odor. However, certain materials were at least promising for one or more of the uses and therefore deserve further consideration. Compounds in the more effective group may be considered

for use against other insects.

PART III. EVALUATION OF MATERIALS AS MOSQUITO LARVICIDES

By C. C. Deonier, E. Hinckey, and H. H. Incho

Screening tests were made on 6,642 organic compounds to determine their toxicity to fourth-instar larvae of Anopheles quadrimaculatus Say. In general this species is more susceptible to toxic agents than is Culex quinquefasciatus Say, which has been used in similar tests by Bushland and King (2) and Pink et al. (7). This report includes an evaluation of all the compounds tested. A more detailed discussion of compounds related to DDT (4) and those toxic at 1 p.p.m. or less is given by Deonier et al. (5).

Early fourth-instar larvae selected at random from laboratory colonies were transferred by means of a gauze dipper to a large crystallizing dish containing distilled water (fig. 3). All larvae used on a given day were of the same age and had been reared under uniform conditions. From this selected population 20 larvae were taken at random for each test.

The toxicity of the compounds was determined in acetone-water suspensions prepared as described by Bushland and King (2). A solution of the compound being tested was made by placing 50 mg. in a 50-ml. volumetric flask and making up the volume with acetone. The compounds insoluble in acetone were finely ground and mixed with a small amount of wetting agent before they were introduced into distilled water and used as water suspensions. These preparations contained 1 part of the test material to 1,000 parts of acetone.

In the initial tests a suspension of the chemical was made by adding 2.5 ml. of the acetone solution to 225 ml. of water in a 400-ml. beaker, after which the larvae in a beaker containing 25 ml. of water were transferred to the larger beaker (fig. 4).

The test beakers were kept in a constant-temperature room at 78°-80° F. The mortality readings were made after 24 and 48 hours. Larvae that were able to come to the surface after being forced to submerge were classed as alive; those unable to do so were considered dead.

An untreated check was used for each lot of larvae. Occasionally cannibalism occurred between the 24- and 48-hour readings and caused undue mortality. In such cases the entire series of tests was discarded and the tests were repeated on a new lot of larvae.

The initial tests were made at a dosage of 10 p.p.m. A compound that gave mortality of 50 percent or less in 48 hours was considered nontoxic and no further tests were made. Those compounds showing toxicity were tested at 10, 1, and 0.1 p.p.m.

In making suspensions of 10 p.p.m. difficulty was encountered in keeping a few of the compounds dispersed. A note was made if a suspension flocculated and a precipitate was formed, or, as was more frequently the case, if the material came to the surface. Those materials which came to the surface naturally gave higher mortalities than the dosage justified, because of the high concentration to which the surface-inhabiting anopheline larvae were subjected. Rarely did a suspension separate at the lower concentrations. When this did occur, more of the compounds passed the initial tests and the possibility of missing a compound showing slight toxicity was decreased.

Discussion of Results

Larvae of Anopheles quadrimaculatus have many desirable characteristics which make them satisfactory as test insects for evaluating the toxicity of synthetic organic compounds. They are not highly resistant to toxic materials, their criterion of death is easily established, and they represent an important group of insects.

Anopheline larvae have some limitations as test insects, chiefly in that they are expensive to rear. Aedes aegypti (L.) and Culex quinquefasciatus could be used just as satisfactorily with materials tested as suspensions. Mosquito larvae show considerable variation from day to day in their susceptibility to toxic materials. In close comparisons of highly toxic materials DDT was used as a standard, but in these tests no standard was used. The various groups cover a rather wide range, and in some tests a compound gave mortalities that were borderline and the class in which it would fall might depend on this daily variation. For example, after extensive tests a material in group 3 might be placed in group 4, or a material in group 4 back in group 3.

Of 74 compounds related to DDT, 24 were not toxic at 10 p.p.m. Because of the high toxicity to mosquito larvae of DDT and certain other synthetic organic compounds (toxic at 0.01 p.p.m. or even lower concentrations), materials rated as 4 in the table may not necessarily be considered good larvicides. However, these materials and possibly those in group 3 may be effective against other insects. Compounds related to those in groups 3 and 4 will no doubt show the greatest promise in the development of new synthetic organic insecticides.

Of the 6,642 materials tested as larvicides, 5,492, or 83 percent,

were rated as 1; 720, or 11 percent, as 2; 218, or 3 percent, as 3; and 212, or 3 percent, as 4.

PART IV. EVALUATION OF MATERIALS AS MITICIDES FOR APPLICATION TO CLOTHING

By F. M. Snyder, F. A. Morton, and H. F. Cross

In early studies at the Orlando laboratory to find a method of treating clothing to prevent chigger or mite (Eutrombicula spp.) attachments, Madden and co-workers (11) found that dimethyl phthalate was effective for several weeks when applied around the openings of garments, provided the garments were not washed. To protect troops in the field, however, it was desirable to find a material that would resist exposure to water and laundering, and in 1944 screening tests were made of nearly 6,000 compounds.

The stopping-time method, adapted from a method originally reported by Maj. R. N. McCulloch of the Australian Army (unpublished), was used. In brief this method consisted in confining five chiggers on a small piece of cotton twill that had been impregnated with a solution of the test material (fig. 5) and observing the time before they were unable to crawl a distance approximately equal to their own length. When dry the impregnated cloth was fastened to a glass slide and the chiggers were confined on it by placing another glass slide over them. The slides were separated by a rubber ring, such as is used for mason jars, and held together with rubber bands (fig. 6). A material was considered to be miticidal if it stopped the chiggers in 15 minutes or less.

The cloth was first impregnated at a rate equivalent to 4 grams per square foot. If a test material was found to be miticidal by this test, it was rinsed in cool water for 48 hours and tested again. For this purpose a mechanical rinsing apparatus was developed. This apparatus consisted of a wooden box, with twelve 1-quart mason jars around its periphery, attached to an electric motor. The materials were placed in the jars containing 600 ml. of water, and rotated at 39 revolutions per minute (fig. 7). If the cloths were still effective, fresh samples impregnated at 2 grams per square foot were prepared. They were washed 10 minutes, in 20 gallons of water at 120° F. with 0.7 percent of soap, in an electric washing machine and rinsed twice for 5 minutes in an equal volume of cool water. Samples were washed and tested until they failed to stop chiggers in 15 minutes.

In the tests with the washed cloths a nonimpregnated cloth and a cloth impregnated with benzyl benzoate were washed and tested concurrently as checks.

Early in this work benzyl benzoate showed such promise that it was tested on a larger scale, and clothing impregnated with it was found to withstand at least two washings (12).

Treatment of clothing with this material was soon adopted by the Army. In the screening tests, therefore, the benzyl benzoate impregnated cloth was also washed and tested as a standard of comparison for the materials found to be miticidal after the 48-hour rinsing.

Of the 5,970 compounds tested, 2,766, or 46 percent, rated as 1; 2,166, or 36 percent, as 2; 874, or 15 percent, as 3; and 164, or 3 percent, as 4.

In 54 tests the benzyl benzoate check cloths failed to stop chiggers as follows: none after the first washing, 6 after the second, 20 after the third, 18 after the fourth, 9 after the fifth, and 1 after the sixth.

PART V. EVALUATION OF MATERIALS AS MOSQUITO REPELLENTS

By F. A. Morton, B. V. Travis, and J. P. Linduska

Tests were made with 6,241 chemicals to determine their relative effectiveness as mosquito repellents. All the materials were tested in the laboratory against Aedes aegypti, most of them against Anopheles quadrimaculatus, and many of them in the field against Aedes taeniorhynchus (Wied.) and other species. Results are presented only for A. aegypti, as it displayed a greater range of response to the repellents and more of the chemicals were tested against this species than against the others.

A test was made by covering the forearms (wrist to elbow) of test subjects with a chemical or a treated cloth and then exposing them in cages containing 2,000 to 4,000 hungry mosquitoes. Both white and colored subjects were used. The mosquitoes were of various ages, since new ones were added each day. Only a few exposures were made in any one cage. The mosquitoes were no longer used when less than 20 would bite on an untreated arm in a half-minute; the usual biting rate was 50 to 75. The tests were conducted in rooms maintained at a temperature of 80°-85° F. and a relative humidity of 80-85 percent.

Skin Applications

Liquids and low-melting solids were tested by distributing 1 ml. of the chemical evenly over the forearms of two to four men. Gloves were worn to protect the hands, and the treated arms were exposed in the cages for 3 minutes at 30-minute intervals, or until the mosquitoes bit (fig. 8). The time between the treatment and the first bite was used as the criterion of effectiveness, and is referred to as the repellent time. Preliminary tests were made of all the chemicals, and most of the promising materials were given

additional tests.

The technique used was a modification of that developed by Granett (8). Granett evaluated most of the chemicals on himself, whereas at Orlando 250 subjects were used during the course of the tests. Consequently, there was a wide range in repellent time owing to individual differences, which provided information on the expected range of effectiveness of the material. The compounds that gave protection for at least 180 minutes were placed in group 4.

Of the 4,137 chemicals tested as skin repellents, 2,336, or 56 percent, were in group 1; 1,161, or 28 percent, in group 2; 279, or 7 percent, in group 3; and 361, or 9 percent, in group 4.

Fabric Impregnations

Solid chemicals, as well as many of the liquids, were tested by applying them to cloth. Early tests indicated that it was necessary to have the cloth in contact with the body to obtain satisfactory results.

A piece of women's mercerized cotton hose was impregnated with the candidate chemical at a rate equivalent to 3.3 grams per square foot. To insure uniform distribution the chemical was applied in a volatile solvent, usually acetone. The hose was spread on a rack to dry, and then hung indoors on a line. The usual procedure was to treat one day and make the first test the following day. Tests were made by drawing the treated portion of the stocking over the forearm (fig. 9) and exposing it for 1 to 2 minutes in the test cages. If five bites were received, the treatment was considered noneffective.

When applied to cloth, repellent materials remain effective for several days, as compared with hours in skin applications. The compounds that remained effective for at least 10 days were placed in group 4.

Of 3,239 chemicals tested as repellents applied to fabric, 1,655, or 51 percent, were in group 1; 529, or 16 percent, in group 2; 257, or 8 percent, in group 3; and 798, or 25 percent, in group 4.

Explanation of Terms and Symbols Used in the Table
Presenting Results of Screening Tests

Lousicides:

Ins. = Insecticidal results (24-hour exposures in beaker tests)

1. Incomplete mortality or paralysis of lice following initial exposure to freshly treated pads.
2. Complete mortality or paralysis of lice following initial exposure, but incomplete kill or knock-down of lice exposed to the pads 1 day after treatment.
3. Complete mortality or paralysis of lice from exposure to pads 2 to 10 days after treatment.
4. Complete mortality or paralysis of lice from exposure to pads 10 days after treatment.

Ov. = Ovicidal results.

1. 0 to 50 percent kill of eggs treated with 5-percent solutions.
2. 51 to 99 percent kill of eggs treated with 5-percent solutions.
3. 100 percent kill of eggs treated with 5-percent solutions and 0 to 99 percent kill with 1-percent solutions.
4. 100 percent kill of eggs with 1-percent solutions or lower concentrations.

K.D. = Knock-down or paralysis of lice after exposure to treated pads.

1. Incomplete or no knock-down within 24 hours.
2. Complete kill or knock-down during the period 3 to 24 hours.
3. Complete kill or knock-down during the period 1 to 3 hours.
4. Complete kill or knock-down within 1 hour or less.

Miticides:

1. Materials not miticidal (4-gram dosage).
2. Materials miticidal (stopping time of 15 minutes or less) before but not after treated cloth was rinsed (4-gram dosage).
3. Materials miticidal before and after treated clothing was rinsed (4-gram dosage) but not effective after three launderings, or else not effective after as many launderings as concurrently tested benzyl benzoate standard (2-gram dosage of each).
4. Materials miticidal after three launderings, or else effective for at least as many launderings as the concurrently tested benzyl benzoate standard (2-gram dosage).

Larvicides (Anopheles quadrimaculatus):

1. Nontoxic or less than 50-percent kill at 10 p.p.m.
2. Mortality 50 to 95 percent at 10 p.p.m.
3. Mortality complete at 10 p.p.m. but less than 50 percent kill at 1 p.p.m.
4. Mortality 50 to 100 percent at 1 p.p.m.

Repellents (Aedes aegypti):

S = Tests as skin treatments.

1. Repels less than 60 minutes.
2. Repels 61 to 120 minutes.
3. Repels 121 to 180 minutes.
4. Repels more than 180 minutes.

C = Tests on treated cloth.

1. Not effective the first day.
2. Effective 1 to 5 days.
3. Effective 6 to 10 days.
4. Effective more than 10 days.

Relative Effectiveness of Chemicals Tested as Insecticides and Repellents*

7006	3967	Zinc sulfate	1	1	1	1		2

Supplement

Item	Orlando:	Chemical	: Lousicide			Miti-: : Larvi-: : Repellent		
No.	: No. O- :		: Ins.:	Ov.:	K.D.:	cide : S : C		
7007	9010	Acetic acid, 1-trichloromethyl- 2,2'-methylenebis-(4,6-di- chlorophenyl) ester	1	1	1	1	4	1
7008	8662	N-Amyl-p-nitrobenzamide	1	1	1	2	1	1
7009	9775	N,N-Bis-(2-(p-chlorophenoxy) ethyl)methylamine	1	2	1	1	3	1
7009a	2372	Bis-(2-hydroxy-3,5,6-trichloro- phenyl)methane	1	1	1		2	
7010	7781	Bis(2,4,6-trichloro-3-hydroxy- phenyl)methane	1	1	1	1	1	1
7011	8659	N-sec-Butyl-p-nitrobenzamide	1	1	1	2	1	1
7011a	1827	n-Caprylic acid, iso-amyl ester	1	1	1	2	1	1
7012	9664	o-Chlorobenzamide	1	1	1	1	1	1
7013	9668	p-Chlorobenzamide	1	2	1	1	1	1
7014	9667	o-Chloro-N-ethylbenzamide	1	2	1	3	1	1
7015	9665	o-Chloro-N-methylbenzamide	1	1	1	1	1	1
7016	9669	p-Chloro-N-methylbenzamide	1	3	1	1	1	1
7017	9009	3-Chloro-alpha-(pentachloro- phenoxy)acetanilide	1	1	1		2	
7017a	7783	o-Chloro-alpha-(trichloromethyl) benzyl alcohol	2	2	2	3	2	4
7018	9013	1,1-Cyclohexane-4,4-bis- (2,6-dichlorophenol)	1	1	1	1	2	1
7019	8455	2-(Dibenzylamino)ethyl penta- chlorophenyl ether	1	1	1	1	1	1
7020	9003	N,N'-Dibenzyl-N'-(2,5-dichloro- phenyl)ethylenediamine	1	1	1	1	1	1
7020a	1963	Di-(p-bromophenyl) ether	4	2	2		4	
7021	7663	alpha,beta-Dibromosuccinic acid	1	1	1	1	2	1
7021a	9766	2,4-Dichlorobenzamide	2	1	2	1	1	1
7022	9769	3,4-Dichlorobenzamide	1	1	1	1	1	1
7022a	9768	2,4-Dichloro-N,N-dimethylben- zamide	3	3	2	2	1	2
7023	9771	3,4-Dichloro-N-ethylbenzamide	1	2	1	1	1	1
7023a	9767	2,4-Dichloro-N-methylbenzamide	2	2	2	1	1	1
7024	9770	3,4-Dichloro-N-methylbenzamide	1	1	1	1	2	1
7025	9002	1-(2,5-Dichlorophenyl)urea	1	1	1		2	
7026	8454	2-(Diethylamino)ethyl penta- chlorophenyl ether	1	1	1	1	1	1
7027	8381	N,N-Di-(2-ethylhexyl)trichloro- acetamide	1	1	1	1	1	1
7028	8371	N,N-Dimethyl-p-nitrobenzamide	1	3	1	1	1	1
7029	9008	N-(2-(2,4-Dinitrophenoxy)ethyl) dibenzylamine	1	2	1	1	2	1
7030	9004	N-2-(Di-iso-propyl-o-toloxyl) ethyldibenzylamine	1	1	1	1	1	1

Item No.	:Orlando: No. 0- :	Chemical	: Lousicide			: Miti- cide	: Larvi- cide	: Repellent S : C
			: Ins.	: Cv.	: K.D.			
7031	9005	N-2-(Di-iso-propyl-m-toloxo) ethyldibenzylamine	1	1	1	1	2	2
7032	7662	2,2'-Dithiobisbenzothiazole	1	1	1		2	
7033	1558	2-Formyl-1-phenylhydrazine	1	22/	1			
7034	7785	9-Hendecenoic acid, alpha-(tri- chloromethyl)benzyl ester	1	1	1	1	2	1
7034a	7784	9-Hendecenoic acid, 1-tri- chloro-2-methyl-2-propyl ester	1	1	1	2	1	4
7035	9006	8-Methyl-1,5-dioxaspiro-(5.5) hendecane-3-ol	1	3	1	2	1	3
7036	9007	9-Methyl-1,5-dioxaspiro-(5.5) hendecane-3-ol	1	3	1	2	2	3
7037	9433	p-Nitrobenzoic acid, iso-amyl ester	1	1	1	4	1	1
7038	8669	p-Nitrobenzoic acid, benzyl ester	1	1	1	1	1	1
7039	9434	p-Nitrobenzoic acid, p-bromo- phenyl ester	1	1	1		1	
7040	8663	p-Nitrobenzoic acid, 2-chloro- ethyl ester	1	2	1	4	1	1
7041	9431	p-Nitrobenzoic acid, o-Chloro- phenyl ester	1	1	1	1	1	1
7042	9432	p-Nitrobenzoic acid, p-chloro- phenyl ester	1	1	1		1	
7043	9000	p-Nitrobenzoic acid, cyclo- hexyl ester	1	1	1	4	2	1
7044	9430	p-Nitrobenzoic acid, 2,4- dinitrophenyl ester	1	4	1	2	1	1
7045	9435	p-Nitrobenzoic acid, 2-naphthyl ester	1	1	1		1	
7046	9429	p-Nitrobenzoic acid, o-nitro- phenyl ester	1	1	1	1	1	1
7047	9001	p-Nitrobenzoic acid, phenyl ester	1	1	1	1	2	1
7048	8664	p-Nitrobenzoic acid, propyl ester	4	1	2	3	1	1
7049	9666	m-Nitrobenzoic acid, 2-(2- pyridyl)ethyl ester	1	1	1	1	1	1
7050	9663	p-Nitrobenzoic acid, 2-(2- pyridyl)ethyl ester	1	1	1	1	1	2
7051	9662	p-Nitrobenzoic acid, tetrahydro- furfuryl ester	1	2	1	1	1	
7052	618	Oil of wormseed, American (Oil of Chenopodium)	1	3	1	2	1	2
7053	1559	1-Phenyl-2-propionylhydrazine	1	1	1			
7053a	4578	1-Phenylsemioxamazide	1	1	1			
7054	1792	Phthalic acid, carboethoxy- methylmethyl ester (Santicizer M-17)	1	1	1	1	1	
7055	1396	N-iso-Propylphthalimide	3	2	2	1	1	1
7056	9773	2,2'-Sulfonylbis-(4-chloro- phenol)	1	1	1	1	1	1
